A detailed technical drawing of a heavy-duty metal safe. The safe is rectangular with a thick door. On the front of the door, there are two circular handles or knobs, one near the top and one near the bottom. A large, heart-shaped keyhole is positioned in the center of the door. To the right of the safe, a large key is shown, featuring a heart-shaped head and a long, straight shaft. The drawing is rendered in a style that suggests a technical or architectural illustration, with fine lines and shading to indicate the metallic texture and mechanical details.

Use Router D to let in the above locks.

ROUTER FOR LETTING IN THE "DUER" LOCKS.

This router is made in three sizes: Size A cuts for locks Nos. 1225 to 1259; size B cuts for 1224, 1227, 1292 and 1293; size D cuts for 1260 to 1291. We keep them in stock with $\frac{1}{2}$ inch spindle, but can furnish them with any sized spindle desired. The cutters are fastened to the head by nuts and bolts, so that when their size is reduced by sharpening they can be set out and the size of the cut maintained. It is all important in setting cutter No. 1, which cuts to let in the back plate of the lock flush with the wood, to so adjust it that it cuts a trifle scant, necessitating the lock to be forced into place; when this is done the lock will remain perfectly secure in the mortise.

EXTRA CUTTERS FOR ROUTER.

A2.

A3.

"DUER" LOCK MACHINE—WITH KEYHOLE ATTACHMENT.

We have found that it is the desire of many of the larger manufactures to have a machine to mortise for these locks alone, so accordingly we have built a small machine occupying only about three square feet of room. This machine is not at all a necessity to those who desire to use our locks, but only a convenience to those manufacturers whose consumption is sufficiently large to justify them in having the best facilities for doing all their work. The above machine routes for the lock and cuts the keyhole, round or oblong, before the wood leaves the machine; thus, with one handling of the wood all hand work is dispensed with. Large manufacturers will appreciate the saving to them in this one item of handling their stuff only once, instead of two or three times as they have to do when using old style locks.

DESCRIPTION OF LOCK MACHINE WITH KEYHOLE ATTACHMENT.

This machine consists of a main hollow column A, which is $4\frac{1}{2}$ feet high, with base 18x22 inches. A plained sideway runs from top to bottom, and upon which the table B, and holding clamps U slide. The lower shaft D is the countershaft, which can be driven from any direction, the pulleys over hanging, and upon which are the pulleys for driving the router and keyhole cutter on spindles E and F. The top spindle E has the router C let in its front end and held by a set screw and is adjustable in and out to suit the lock. Spindle F has the keyhole bit K in its front end and is hung in a vibratory frame which is adjustable sideways by thumbscrews N. This spindle has a horizontal movement by the lever M. The table B is held in position on side rods H by the set screws G, and is adjustable up and down from 4 to 24 inches to suit the width of wood to be routed. The holding clamp U has two threaded gauge rods I and J, with four lock nuts on each. The nuts on J are set to fix the depth of rout for lock, and on I for the keyhole. The pivoted lever T is swung out of contact when rout is being made for lock. The holding clamp U has a piece of hard wood screwed to its underside, through which the router C passes. The cam lever O is for clamping the front in firmly while the routing is done. The rod P is fastened to the table B and passes up through the cam lever O and lugs on holding clamp U and acts as the pivot for cam lever O to swing on. The treadle L is pivoted to side of main column and is suspended to rods H by means of chains over the sheave rollers at top of column. There is a rod, not shown in the cut, screwed into side of holding clamp upon which is an adjustable stop for locating rout in the wood.

DIRECTIONS FOR OPERATING LOCK MACHINE.

Lower the holding clamps U so that the router C will be above the hard wood block that is screwed to its under side. Raise table B by the set screws G, so that the distance from top of table B to underside of hard wood block will be, say, $\frac{1}{4}$ of an inch more than the width of the wood to be routed. Set the stop on the rod which is screwed into holding clamp U, not shown in the cut, the required distance. Put in the wood to be routed, place the foot on the treadle and press sufficiently to bring the top of piece in contact with the hard wood block, then swing around the cam lever O, which clamps the piece and also holds the table B and clamp U together by the action of the lever O on the rod P. The nuts on gauge rods I and J having been set the required depth for rout of lock and location of keyhole, and lever T being swung out of contact, press on treadle L until bottom nuts on J come to the stop, then lower the whole arrangement without loosening lever O, and swing lever T around in position between the nuts on rod I, bring spindle F forward by lever M, until cutter K cuts through the piece and cuts into hard wood block on bottom of swinging lever, then raise and lower table until keyhole rout is made. This is done when keyhole is oblong. When it is round of course there is no movement up and down. The spring on F throws it back into place. The position of keyhole sidewise is regulated by the thumbscrews N. Rout and keyhole now being made, lower table and loosen cam lever O, when machine is ready for next rout. The hard wood piece screwed under the holding clamp U is to prevent the splintering of mouth of wood when routed, and must be changed for each different size of locks. The cutter must cut through this piece of wood first.

THE RELIABLE EXTENSION TABLE SLIDE.

PATENTED.

[We are Sole Agents for this Slide.]

We call your attention to the above table slide, which we believe to be the very best in the market, for the following reasons:

It is well made of seasoned lumber of superior quality, and every set is guaranteed to work freely and smoothly. It will wear longer than any slide in which the wearing surface is iron upon wood; in this Slide it is wood upon wood, in which there is less friction, and therefore less wear. It is made with a bevel or shoulder at A, where the sections are screwed to the table, thus keeping the balance of the Slide clear of the table top. All table-makers will appreciate this simple yet valuable improvement, which saves both time and labor, and adds to the freedom of its action.

No. 1. FOR SQUARE FRAMES.
